

## Report on Adaline and Perceptron Results

### Adaline Model Analysis

#### 1. High-Performance Combinations:

- For classes **A** and **B**, several combinations achieved a perfect 100% accuracy, including:
  - gender & fin length
  - body mass & beak depth
  - body mass & fin length
  - beak length & beak depth
  - beak length & fin length
  - beak depth & fin length

- Similarly, for **A** and **C**, combinations like gender & beak length and body mass & beak length also reached 100% accuracy.

- For **B and C**, high accuracy was achieved with gender & beak depth, body mass & beak depth, and beak length & beak depth combinations.

2. **Conclusion:** The consistent high performance of pairs involving **beak depth**, **beak length**, and **fin length** suggests that these features are particularly effective in distinguishing between species A and B, B and C, and to some extent, A and C.

3. **Low-Performance Combinations:**

- For classes **A and C**, some feature pairs yielded notably low accuracy:
  - **gender & body mass** (40%)
  - **gender & beak depth** (43.33%)

- For **B** and **C**, **gender** & **beak length** showed a lower accuracy of 60%.

4. **Conclusion:** The lower accuracy when using **gender** in combination with other features (especially **body mass** or **beak depth**) suggests that **gender may be a less informative feature** for distinguishing between species A and C, and sometimes B and C.

## Perceptron Model Analysis

### 1. High-Performance Combinations:

- Similar to Adaline, the Perceptron model achieved 100% accuracy with several feature combinations for **A** and **B**:

- gender & fin length
- body mass & beak depth
- beak length & beak depth

- For **A** and **C**, 100% accuracy was also achieved with pairs like gender & beak length and body mass & beak length.

- In **B and C**, combinations including **beak depth** and **fin length** (like **gender & beak depth**, **body mass & beak length**, and **beak length & beak depth**) frequently achieved high accuracy.
2. **Conclusion:** The Perceptron model, like Adaline, shows that **beak depth**, **beak length**, and **fin length** are effective at separating species across all pairs, with **body mass** also showing some utility.
  3. **Low-Performance Combinations:**

- For classes **A** and **C**, using **gender** in combination with other features resulted in notably lower accuracy:
  - **gender & body mass** (50%)
  - **gender & beak depth** (50%)

- For **B** and **C**, **gender & beak length** resulted in a lower accuracy of 60%.

4. **Conclusion:** These results confirm that **gender and beak depth** are less informative, especially for distinguishing species pairs like A and C, or B and C. This trend is consistent across both models.

## Feature Discrimination and Conclusion

Based on the results across different feature combinations and species pairs:

- **Most Discriminative Features:** **Beak depth, beak length, and fin length** are the most effective features for separating species pairs across both models. This suggests these features capture significant species-specific characteristics.
- **Least Discriminative Feature:** **Gender** shows inconsistent performance, particularly when combined with **body mass** or **beak depth** for certain species pairs. This suggests it may not be a reliable feature for classification on its own.

## Final Note on Highest Accuracy Features

The highest accuracy across both models was achieved with combinations involving **beak length, beak depth, and fin length**. These features consistently supported accurate classification, indicating that they are the most valuable for distinguishing between species A, B, and C in this dataset.
